Computer Engineering (CMPEN)

CMPEN 111: Computers and Computer Hardware
1 Credits

A brief orientation to University life and resources and an introduction to computers and computer hardware. CMPEN 111S Computers and Computer Hardware (1) This course contains two components: an orientation to University life and an introduction to the hardware aspects of computer engineering. In the orientation to University life, students learn about the responsibilities of and expectations on a student including ethical behavior, and explore some of the academic and non-academic resources of the University. In the introduction to computer engineering students learn about some of the fundamental concepts, devices, and methodologies that are involved in the design and use of digital and computer hardware. This exploration begins with a foundation of logic and critical thinking. Logic is examined first from a theoretical problem solving standpoint. The discussion then progresses to an implementation perspective examining how logic devices are created and used. Included is a look at some CAD tools and some logic design laboratory exercises. Using logic as a basic building block, the organization and design of a computer is then examined, ending in an exploration of some of the contemporary methods used to make computers faster and more efficient.

First-Year Seminar

CMPEN 270: Digital Design: Theory and Practice
4 Credits

Introduction to digital design techniques and design. Topics include combinational and sequential devices and circuits, modern design tools and design practices. Students may take only one course for credit for CMPEN 270 or 271 and CMPEN 270 or 275. CMPEN 270 Digital Design: Theory and Practice (4) CMPEN 270 is a first course in digital systems and digital system's design. It lays the groundwork for many later courses in computer organization and architecture and switching theory. The course includes both a lecture component to introduce important concepts, principles, methodologies and theories and a laboratory component in which the lecture material can be applied and practiced. The course introduces the theoretical foundation for digital systems including number systems, a variety of commonly used codes and Boolean algebra. Combinational devices, logic gates, and sequential devices, latches and flip-flops are introduced along with design techniques, methods and tools. Design criteria and objectives are considered and design trade-offs are examined. Higher level design elements are also examined such as decoders, multiplexers, counters, and registers, and their use in system design. Students are exposed to a variety of design tools and implementation techniques, including schematic capture tools, simulation tools, Hardware Description Languages (HDL) and HDL design tools. Laboratory work includes the design, construction and debugging of a variety of digital circuits, and the use of standard laboratory tools such as the oscilloscope and logic analyzer, and various software design tools.

Concurrent: PHYS 212

CMPEN 275: Digital Design Laboratory
1 Credits

Introduction to digital design techniques. Students may take only one course for credit for CMPEN 270 or 275.

Concurrent: CMPEN 271; PHYS 212

CMPEN 296: Independent Studies
1-18 Credits/Maximum of 18

Creative projects, including research and design, that are supervised on an individual basis and that fall outside the scope of formal courses.
Writing Across the Curriculum

Prerequisite:
techniques of reporting their technical designs.

Being a writing-across-curriculum course, students will learn effective
design, implement, and validate application specific embedded systems.

Intended to be general-purpose computers. In the laboratory students will
systems are based on microprocessors and microcomputers, but are not
applications, personal computing, and consumer products. Embedded
systems are increasingly important as they are used in industrial
engineering and computer science majors. CMPEN 331 requires access to
PCs/workstations with commercial hardware description language tools
(e.g., Synopsys VSS compiler and simulator) and a modern assembler/
debugger (e.g., SPIM MIPS assembler, simulator, and debugger).

Prerequisite: CMPEN271 or CMPEN270; CMPSC121 or CMPSC201

CMPEN 351: Microprocessors

3 Credits

Microprocessor architecture; memory system design; assembly language
programming; interrupts; the stacks and subroutines; memory and I/O inter-
facing; serial I/O and data communications; microprocessors
applications.

Prerequisite: CMPEN271; CMPEN275

CMPEN 352W: Embedded Systems Design

3 Credits

Design/development of embedded systems for data acquisition, process
control, and special-purpose computing systems; peripheral interfacing,
serial/parallel communications and bus systems. CMPEN 352W
Microprocessor-based System Design (3) In this course students learn
how to design application specific embedded systems. Embedded
systems are increasingly important as they are used in industrial
applications, personal computing, and consumer products. Embedded
systems are based on microprocessors and microcomputers, but are not
intended to be general-purpose computers. In the laboratory students will
design, implement, and validate application specific embedded systems.
Being a writing-across-curriculum course, students will learn effective
techniques of reporting their technical designs.

Prerequisite: CMPEN351 or CMPEN472; E E 210

Writing Across the Curriculum

3 Credits

Data transmission, encoding, link control techniques; communication
network architecture, design; computer communication system
architecture, protocols. CMPEN 362 CMPEN (E E) 362 Communication
Networks (3) CMPEN (E E) 362 is an elective course in both the electrical
and computer engineering curricula which provides an overview of
the broad field of data and computer communications. First, a general
model of the communication task is presented, including the layered
concept by which each layer provides services for the layer above.
First, the lowest (physical) layer is studied. This involves signal design,
Fourier analysis representations, bandwidth concepts, transmission
impairments and communication media properties. Then the next
higher (link) layer is considered which involves organizing bits into
frames, data link and error control methods (including frame sequence
numbering and error detection principles). Multiplexing to share a link
is studied, including frequency division multiplexing, dedicated time
division multiplexing, and statistical time multiplexing. At the network
layer level, there are two categories: broadcast (usually local area) and
switching networks. Broadcast and local area network studies include
bus, tree and star topologies, Ethernet, optical fiber bus networks,
ring networks, and medium access control protocols. Switching and
routing concepts for networks are explained, including both circuit and
packet switching, datagrams and virtual circuits. Properties of frame
relay and asynchronous transfer mode (ATM) networks are described.
Internetworking frame structures, routing and protocols are studied. Also,
bridge routing for local networks is described. At the still higher transport
(network end-to-end control) layer, transport protocols, including TCP/EP,
are described.

Prerequisite: CMPEN270 or CMPEN271; Concurrent: STAT 301 or
STAT 318 or STAT 401 or STAT 414 or STAT 418
Cross-listed with: EE 362

CMPEN 371: Advanced Digital Design

3 Credits

Theory, design, and implementation of digital circuits based on
combinational and sequential circuits; implementation of designs using
hardware description language. CMPEN 371 Advanced Digital Design
(3) Students will learn advanced concepts in digital design for complex
combinational and sequential logic, and learn how to effectively use
minimization and synthesis techniques. Contemporary CAD tools and
target digital technologies including Field Programmable Gate Arrays
(FPGAs) are utilized. The use of a hardware-description language for
digital design is introduced. In the laboratory portion, students will
implement, simulate, and test designs.

Prerequisite: CMPEN271; CMPEN275; CMPSC121 or CMPSC201; E E
210 or E E 211

CMPEN 395: Internship

1-18 Credits/Maximum of 18

Supervised off-campus, nongroup instruction including field experiences,
practica, or internships. Written and oral critique of activity required.

Prerequisite: prior approval of proposed assignment by instructor
CMPEN 396: Independent Studies
1-18 Credits/Maximum of 18
Creative projects, including research and design, that are supervised on
an individual basis and that fall outside the scope of formal courses.
CMPEN 396A: Current Technologies in Computer Engineering
1-6 Credits
Investigation of a current technology relevant to computer engineering.
CMPEN 397: Special Topics
1-9 Credits/Maximum of 9
Formal courses given infrequently to explore, in depth, a comparatively
narrow subject that may be topical or of special interest.
CMPEN 399: Foreign Studies
1-12 Credits/Maximum of 12
Courses offered in foreign countries by individual or group instruction.
International Cultures (IL)
CMPEN 411: VLSI Digital Circuits
3 Credits
Basic building blocks of CMOS design, design rules, chip planning, layout
design, system power and timing, simulation of VLSI structures.
Prerequisite: CMPEN371 or CMPEN471 ; E E 310
CMPEN 416: Digital Integrated Circuits
3 Credits
Analyses and design of digital integrated circuit building blocks, including
logic gates, flip-flops, memory elements, analog switches, multiplexers,
and converters. CMPEN 416CMCPEN 416 Digital Integrated Circuits
(3)CMPEN 416 is a technical elective available to electrical and computer
engineering students. It is intended for students who wish to specialize
in the field of digital circuits. This course introduces the basic concepts
involved in the design of digital circuits, which find practical application
as logic and memory circuits in computers and other digital processing
systems. The course emphasizes integrated circuit process-compatible
circuit design techniques in recognition of the amazing synergy that
has characterized the relationship between computer circuits and
integrated circuit processing technology. This course includes three
lectures and a two-hour laboratory each week. The only prerequisite is
E E 310, a basic circuits course required for both electrical engineering
and computer engineering students. CMPEN 416 begins with a review of
the bipolar junction transistor (BJT) device and proceeds into the more
advanced Ebers-Moll device model. This is followed by an examination
of a series of BJT-based saturating and non-saturating digital circuits
of ever increasing complexity illustrating the evolution of the modern
bipolar logic circuit families. The next phase of the course reviews the
metal oxide semiconductor field effect transistor (MOSFET) and proceeds
along the same path taken for the bipolar transistor circuits. Various
MOSFET logic circuit families are introduced and analyzed. Computer
semiconductor memory circuits are considered next. Both BJT and
MOSFET versions of both static and dynamic read-write and read-only
memories are considered. The cell array, memory addressing circuits,
and sense amplifier designs are all examined in detail. This is followed
by the related subject of programmable logic arrays, the final topic. The
emphasis of the laboratory component of the course is to compare the
performance of representatives of each class of circuits to computer
simulations of the same circuits. Parameters such as input-output
voltage transfer characteristics, noise margins, and propagation delays
are evaluated by building and measuring laboratory models. Most of the
laboratory exercises require the student to evaluate a specified circuit,
but the final exercise requires the student to design a circuit to meet
a predefined set of specifications, then to prove that the design meets
the requirements by measuring the circuit performance. Students are
required to write a formal engineering report detailing the results of each
laboratory exercise.
Prerequisite: E E 310
Cross-listed with: EE 416
CMPEN 417: Digital Design Using Field Programmable Devices
3 Credits
Field programmable device architectures and technologies; rapid
prototyping using top down design techniques; quick response systems.
CMPEN 417CMPEN (E E 417 Digital Design Using Field Programmable
Devices (3)Field Programmable Devices, such as Field Programmable
Gate Arrays (FPGAs) and Complex Programmable Logic Devices (CPLDs)
are widely used for rapid prototyping and quick response-time designs.
The objective of this course is to introduce the student to digital design
using Field Programmable ICs, and to provide an understanding of
the underlying technologies and architectures of these Integrated
Circuits. The course begins by introducing design alternatives for modern
electronic systems identifying and classifying alternative system
solutions, and evaluating when particular design solutions are optimal.
These alternatives include microprocessors, microcontrollers, off-the-
shelf digital ICs, Programmable logic ICs (FPGAs and CPLDs), and
various forms of Application Specific Integrated Circuit (ASIC) designs.
A homework assignment requires the student to quantitatively evaluate
the cost, complexity, packaging, and time-to-market issues for a complex
system design specification. Next, the underlying Field Programmable
Logic IC architectures and technologies are studied in detail. Following
a broad survey of available programmable IC vendors and on-chip
programming technologies (and their cost/performance trade-offs),
several specific case studies are presented in the class. The first is
the Xilinx XC4000xl line, because of the target boards used in the CAD
laboratory component for this class. The initial lab portions of the class
help the students to specify their design using various forms of design
entry tools and also allows them to see how their design map on to the
underlying FPGA architecture. The students also learn the underlying
algorithms used by the design software they use in their Labs. Next, the
systematic top-down method for specifying complex designs using VHDL
is introduced. Students are given a supporting homework assignment
to develop high-level behavioral models for a simple digital system to
reinforce this segment of the course. VHDL behavioral synthesis is now
introduced as a preferred path to go from high-level system behavior to
actual implementation on the FPGA. The strengths and weaknesses of
synthesis are discussed, as are the emerging CAD tool trends. Additional
VHDL-based homework assignments reinforce behavioral design and
synthesis using commercial CAD tools. The final segment of the class
covers special topics that identify current trends in digital system
architecture and programmable logic design. These include such topics
as partially reconfigurable architectures and dynamic reconfiguration
techniques, system design for testability, and field programmable
analog arrays. Applications of FPGAs in special purpose computing
environments such as signal processing, Java acceleration and image processing are also introduced. In the laboratory, student design project assignments explore larger and more complete system specifications of such things as controllers, CPU and memory design, and signal processing blocks. These assignments reinforce the lecture content as the students model, synthesize and implement their digital designs on the target Xilinx FPGA boards.

**Prerequisite:** CMPEN331
Cross-listed with: EE 417

**CMPEN 431: Introduction to Computer Architecture**

3 Credits

Introduction to computer architecture. Memory hierarchy and design, CPU design, pipelining, multiprocessor architecture. CMPEN 431 Introduction to Computer Architecture (3) This course will introduce students to the architecture-level design issues of a computer system. They will apply their knowledge of digital logic design to explore the high-level interaction of the individual computer system hardware components. Concepts of sequential and parallel architecture including the interaction of different memory components, their layout and placement, communication among multiple processors, effects of pipelining, and performance issues, will be covered. Students will apply these concepts by studying and evaluating the merits and demerits of selected computer system architectures.

**Prerequisite:** CMPEN331 or CMPEN371

**CMPEN 431H: Honors Introduction to Computer Architecture**

3 Credits

Honors course in principles of computer architecture: memory hierarchies and design, I/O organization and design, CPU design and advanced processors. CMPEN 431H Introduction to Computer Architecture (3) This course will introduce students to the architecture-level design issues of a computer system. They will apply their knowledge of digital logic design to explore the high-level interaction of the individual computer system hardware components. Concepts of sequential and parallel architecture including the interaction of different memory components, their layout and placement, communication among multiple processors, effects of pipelining, and performance issues, will be covered. Students will apply these concepts by studying and evaluating the merits and demerits of selected computer system architectures.

**Prerequisite:** CMPEN331

**CMPEN 441: Operating Systems**

3 Credits

Resource management in computer systems. Process scheduling, memory management, file system design, I/O management, Unix operating system.

**Prerequisite:** CMPSC360

**CMPEN 454: Fundamentals of Computer Vision**

3 Credits

Introduction to topics such as image formation, segmentation, feature extraction, matching, shape recovery, object recognition, and dynamic scene analysis. CMPEN 454 Fundamentals of Computer Vision (3) CMPEN 454 is an introduction to computer vision. The goal of computer vision is to make computers understand and interpret visual information. Computer vision systems bring together imaging devices, computers, and sophisticated algorithms for solving problems in areas such as industrial inspection, medicine, document analysis, autonomous navigation, and remote sensing. The course involves both pedagogical written assignments and computer projects. The beginning of the course gives an overview of computer vision and introduces low level image analysis techniques for binary images. Binary vision systems are useful when the silhouette of an object conveys enough information to recognize it. Examples can be found in optical character recognition, chromosome analysis, and recognition of industrial parts. Moreover, many techniques developed for binary systems can be applied to gray level or color images. Next, the course covers image segmentation and contours. These topics are the foundation of most computer vision techniques. For an image to be correctly interpreted, it must be partitioned into regions that correspond to distinct objects or parts of objects. First, region-based techniques such as thresholding, split and merge, region growing and texture analysis are introduced. Next, edge-based techniques using gradient and Laplacian operators are discussed. Finally, contour representations and curve approximations linking edges into region boundaries are studied. Next, depth from vision, with emphasis in stereo vision, is considered. Calculating distances to and among various points in the scene is important in many computer vision tasks such as inspection, robot manipulation, and autonomous navigation. In this part of the course the geometry of stereo systems and how to obtain depth maps from stereo image pairs is studied. Also, alternative 3D imaging sensors such as laser range finders and radars are discussed. Following stereo, the topic of computer vision is broadened to understand sequences of images over time. In this section techniques using information on spatial and temporal changes are used to design computer vision systems capable of coping with moving and changing objects, changing illumination and changing viewpoints. Visual motion is important primarily for two reasons. First, motion is a very important cue to understand the scene structure. Second, biological systems do use motion to infer properties of the surrounding world with very little a priori knowledge. Finally, the topic of 3D object recognition is discussed. Object recognition entails two main issues: object identification and object localization. Identification determines the objects being imaged while localization determines their position in the world and with respect to the sensors. This topic builds upon all the different techniques discussed until this point.

**Prerequisite:** MATH 230 or MATH 231 ; CMPSC121 or CMPSC201
Cross-listed with: EE 454

**CMPEN 455: An Introduction to Digital Image Processing**

3 Credits

Overview of digital image processing techniques and their applications; image sampling, enhancement, restoration, and analysis; computer projects. E E (CMPEN) 455 An Introduction to Digital Image Processing (3) E E/CMPEN 455, a technical elective available to both electrical and computer engineering seniors and graduate students, discusses many current techniques for processing and manipulating digital images. The course involves both pedagogical written assignments and computer projects. The beginning of the course gives an overview of digital image processing systems and digital image fundamentals. During this unit, important elements of human visual perception are reviewed; these ideas help motivate many of the computer-based techniques described in subsequent units. Also, the standard model for a digital image, in
addition to the concepts of sampling and quantization, are described. Finally, basic topological concepts between digital image pixel are discussed. The next unit considers image transform analysis, with a primary focus on Fourier-based techniques. The one-dimensional Fourier transform is reviewed, and then two-dimensional Fourier transform analysis is discussed. To bridge the gap from the continuous world to the digital world, the sampling theorem is introduced. Next, the Discrete Fourier Transform and its properties are described. Fourier-based filtering techniques, such as the ideal low-pass and Butterworth filters are then introduced. The Fast Fourier Transform is also discussed. Finally, the Discrete Cosine Transform, used later in JPEG and MPEG, is introduced.

The next unit discusses techniques for image enhancement and segmentation. These techniques include point-based techniques based on histogram analysis. They also involve linear and nonlinear mask-based methods for noise reduction and region sharpening. Further, techniques of mathematical morphology, which involve an application of set-theoretic concepts to image processing, are described. Finally, image segmentation methods, based on edge detection and thresholding, are described. The final unit considers the concept of image compression. Techniques for image encoding and decoding are discussed. A brief model of the encoding-decoding process is described. Next, compression techniques, such as run-length encoding and Huffman coding, are described. Finally, the multimedia image-compression methodologies, JPEG and MPEG, are discussed.

Prerequisite: E E 350 or E E 353 ; CMPSC201 or CMPSC121

Cross-listed with: EE 455

CMPEN 461: Communication Networks
3 Credits

Data transmission, encoding, link control techniques, network architecture, design, protocols, and multiple access. CMPEN 461 Communication Networks (3) This course introduces students to fundamental concepts and principles underlying data communication networks, with an emphasis on the Internet and its five-layer architecture: the application, transport, network, link, and physical layers. The fundamental issues to be covered include, but not limited to, reliable communication over an unreliable network layer, connection establishment/teardown and handshaking, congestion and flow control, path determination, multiple access control. The student learning these principles will gain knowledge that lasts long after today’s network standards and protocols have become obsolete.

Prerequisite: CMPEN271 ; CMPSC121 or CMPSC201

CMPEN 462: Wireless Communications Systems and Security
3 Credits

This course explores the fundamental concepts and engineering processes of wireless communication systems, sensors, and security algorithms through the design, implementation, and evaluation of next generation wireless network architectures, and network and cryptographic protocols. This course is intended as a senior level course for computational majors such as computer science and computer engineering since it covers hardware and software design concepts associated with wireless access, data transmission, and computational security, security models, and privacy in a broad range of settings. The first part of the course studies programmatic, computational, and engineering issues associated with wireless systems and sensors at the physical protocol layer. Hardware, software, and engineering design considerations associated with MIMO, low latency, high reliability, and high data rate constraints will be analyzed. The next part of this course will introduce virtual machines, function virtualization, and network-slicing for constraint matching, resource scheduling, and mobility management at the data link and network protocol layers. The final component of the course focuses on the security and privacy for wireless systems and sensors including models and algorithms. The design and implementation of cryptographic algorithms for cellular, Wi-Fi, Bluetooth, Zigbee, and next generation systems including Device to Device (D2D), Vehicle to Vehicle (V2V), and Machine Type Communications (MTC) are studied and analyzed. Upon completion of the course students will be able to critically analyze the design, implementation, and protocols associated with wireless systems and sensors and assess the computational security and privacy vulnerabilities associated with these systems.

Prerequisites: CMPEN 362 or EE 362

CMPEN 471: Logical Design of Digital Systems
3 Credits

Basic switching theory and design of digital circuits, including combinational, synchronous sequential, and asynchronous sequential circuits.

Prerequisite: CMPEN331

CMPEN 472: Microprocessors and Embedded Systems
3 Credits

Microprocessors: architecture, design, assembly language, programming, interfacing, bus structure, and interface circuits and their use in embedded systems. CMPEN 472 Microprocessors and Embedded Systems (3) In this course students should learn about the operation and design of microprocessor-based systems, including both hardware and software aspects with an emphasis on real time control environments and embedded systems. After completing the course, students should be able to develop, write and debug programs in a microprocessor’s assembly language and use standard assembly language program development tools. They should also be able to interpret and analyze basic microprocessor system hardware. This course is a senior level elective for students in computer engineering and computer science. The course requires the use of general department computing facilities consisting of UNIX workstations running the appropriate program development tools.

Prerequisite: CMPEN331

CMPEN 473: Microcomputer Laboratory
3 Credits

Design of digital systems using microprocessors. CMPEN 473 Microcomputer Laboratory (3) This laboratory course provides senior students with both theory and practice in designing, implementing, and debugging microprocessor-based systems. Students are guided through a series of projects in which they design, develop, and implement all of the components in a microprocessor-based single-board system. After completing the course students will be able to design microprocessor-based systems, including both software and hardware design. Students will also be able to use standard system design tools including standard laboratory equipment. This course is a senior level elective for computer engineering majors. CMPEN 472 is a prerequisite for this course. The course requires the use of a design laboratory including standard test
equipment such as an oscilloscope, logic analyzer and signal generator as well as a PC with appropriate design software and a microprocessor or EPROM emulation system.

**Prerequisite:** CMPEN472

**CMPEN 475: Functional Verification**

3 Credits

Introduce concepts, methods, and technology for effective functional verification of modern electronic systems. CMPEN 475 Functional Verification (3)Verifying design correctness of increasingly complex system-on-chip designs poses a major challenge to the semiconductor industry. Functional or logic errors in a chip design that are not identified early in the design phase can dramatically increase a project’s overall cost and schedule. Further, design verification is consuming an ever-increasing portion of IC development time and cost. As much as 70% of effort in a complex IC design project is now attributed to verification. This course will cover five key aspects of verification: an introduction to verification; a detailed description of simulation-based dynamic verification; formal verification; verification methodologies and advanced techniques; and case studies. First, the course will place verification in the context of the chip design process and introduce the verification cycle. Then, it will cover essential methodology principles and introduce the first hands-on example. It will also delve into various topics in dynamic verification, including the basic constructs of stimuli, monitors, checkers, observations categories, assertions, and test benches. Various case studies on actual industry and research designs will be provided. The course will be supplemented by lab-assignments that provide hands-on experience to experiment with methodologies taught in lectures.

**Prerequisite:** CMPEN331

**CMPEN 480: Computer Engineering Design**

3 Credits

Engineering design and modeling, engineering economy, project planning, capstone project selections, and technical communication skills.

CMPEN 480 Computer Engineering Design (3) This course prepares senior computer engineering students for industrial engineering design and project management. It covers the engineering design process, project planning and evaluation, engineering ethics, and engineering economy. In addition, students select, specify, and start their capstone design project, which is completed, in the follow-up course, CMPEN 481. Students are expected to carry out a group design project that is on par with industrial expectations. Upon completion of this course a student should have a solid understanding of the engineering design process, a clear capstone project description, should have completed some preliminary design work, and be adequately prepared to complete the project in CMPEN 481.

**Prerequisite:** CMPEN352W; CMPEN431

**CMPEN 481: Computer Engineering Project**

3 Credits

Group or individual design projects in the area of computer engineering.

**Prerequisite:** CMPEN480

**CMPEN 482W: Computer Engineering Project Design**

3 Credits

Computer engineering design project, project management, documentation, reporting, and group and individual communication skills. CMPEN 482W Computer Engineering Project Design (3) The two principle goals of CMPEN 482W are (1) to introduce the fundamentals of systems engineering and systems engineering management, and (2) to develop written and oral communication skills. The course explore the process of translating a problem statement into an effective and economical computer system that meets the needs of the customer. Topics include a comparison of popular process models, analysis and derivation of requirements, requirements allocation and flow down, the work breakdown structure, object-oriented analysis and modeling, the design and development of the user interface, reliability engineering, scheduling, costing, and ethics. Communication skills are developed through oral presentations and a sequence of writing assignments, beginning with a description of requirements and leading to a final design document. CMPEN 482W is not a prerequisite for any other course. CMPEN 482W requires access to PCs or Unix workstations having a C++ compiler. Other specialty hardware or software may be required on a semester-by-semester basis.

**Prerequisite:** E E 310; E E 353; CMPSC 473; ENGL 202C

**Writing Across the Curriculum**

**CMPEN 494: Research Project**

1-12 Credits/Maximum of 12

Supervised student activities on research projects identified on an individual or small-group basis.

**CMPEN 494H: Research Project**

1-12 Credits/Maximum of 12

Supervised student activities on research projects identified on an individual or small-group basis.

**Honors**

**CMPEN 495: Internship**

1-18 Credits/Maximum of 18

Supervised off-campus, nongroup instruction including field experiences, practica, or internships. Written and oral critique of activity required.

**Prerequisite:** prior approval of proposed assignment by instructor

**CMPEN 496: Independent Studies**

1-18 Credits/Maximum of 18

Creative projects, including research and design, that are supervised on an individual basis and that fall outside the scope of formal courses.

**CMPEN 497: Special Topics**

1-9 Credits/Maximum of 9

Formal courses given infrequently to explore, in depth, a comparatively narrow subject that may be topical or of special interest.
CMPEN 499: Foreign Studies

1-12 Credits/Maximum of 12

Courses offered in foreign countries by individual or group instruction.

International Cultures (IL)
